

# 13 Symmetry Protected Topological phases (SPT)

Quantum phases of matter in 1D (gap,  $T=0$ )

Two states are in the same phase iff there exists a local unitary that transforms one into the other:

$$U = T e^{-i \int_0^1 ds H(s)}$$

Schematic phase diagram:  $P_1$

SB1	SB2
SPT1	SPT2
trivial	

$P_2$

SB  $\hat{=}$  Spontaneous sym. breaking (Landau theory).

Trivial  $\hat{=}$  Adiabatically connected to sym. product state.

SPT  $\hat{=}$  Phase of matter is not characterized by SB but instead it is protected by a symmetry.

## Example

S=1 chain with single ion anisotropy

$$H = \sum [\vec{S}_i \cdot \vec{S}_{i+1} + D \cdot (S_i^z)^2]$$

Symmetries: Translation,  $\mathbb{Z}_2 \times U(1) \supseteq \mathbb{Z}_2 \times \mathbb{Z}_2$ , TR, Inversion

How to distinguish the phases?

### 13.1 Bosonic SPT order in 1D

1D SPT stabilized by different symmetries: on-site, TR, inversion, ...

Focus on **on-site symmetries**, e.g. spin flip symmetries:

#### Projective representations

Operators  $U(g)$  form a projective representation (PR) if

$$U(g) \cdot U(h) = e^{i\phi_{gh}} \cdot U(gh),$$

$\{e^{i\phi_{gh}}\}$  is the factor set (fulfills consistency cond.: Associativity).

[2-cocycle  $G \times G \rightarrow U(1)$ ]

If  $\forall gh: \phi_{gh} = 0$ , the representation is linear.

Allowing to change the phases  $U'(g) = e^{i\alpha} \cdot U(g)$ , which PR can be transformed into each other?

$$\phi'_{gh} = \phi_{gh} + \alpha_{gh} - \alpha_g - \alpha_h$$

Equivalent PR belong to the same cohomology class  $H^2(G, U(1))$

Example  $\mathbb{Z}_N : \{1, R, R^2, \dots, R^{N-1}\}$

$$R^N = 1 \Rightarrow U^N = e^{i\phi} 1$$

Redefinition  $\tilde{U}_R = e^{-i\phi/N} U_R$  removes the phase: All pr. rep. equivalent

Example:  $\mathbb{Z}_2 \times \mathbb{Z}_2 : \{1, R_x, R_z, R_x R_z\}$

$$U_x^2 = U_z^2 = 1$$

$$R_x R_z = R_z R_x \Rightarrow U_x U_z = e^{i\phi} U_z U_x$$

Phase  $\phi = 0, \pi$  cannot be removed: 2 classes  
[Integer/half integer representation]

### Classification of 1D SPT

$|\psi\rangle$  symmetric under  $\otimes_j U_j(g)$  with  $U_j(g)$  being a linear on-site representation of  $g$ :

$\times$  dimensional

Projective representation

$$\Gamma \circledast u = e^{i\theta} \quad \downarrow \quad V \Gamma V^\dagger, [V, \Lambda] = 0$$

linear representation  
of  $g \in G$

The projective representation together with the phase  $e^{i\theta}$  classify different SPT.

Sketch of a proof:

1.) Combine  $n$  transfer matrices  $\tilde{T}_{\lambda\lambda', \beta\beta'} = \frac{\text{PA} \text{PAPA}}{\text{P}\lambda \text{P}\lambda \text{P}\lambda}$ .

If  $n \gg 5$ , we can write  $\tilde{T}_{\lambda\lambda', \beta\beta'} = \bigcirc \hat{\Lambda}$ .

This expression can be decomposed

$$\tilde{T}_{\lambda\lambda', \beta\beta'} = \sum_i \hat{A}_{\lambda\beta}^i \tilde{A}_{\lambda'\beta'}^{i*}$$

with  $\tilde{A}_{\lambda\beta}^{(i, \beta)} = \bigcirc \hat{\Lambda}$  being the fix-point MPS.

(same entanglement as the original MPS)

2.) Study the fix point MPS:

a) Without symmetry: we can always find a local unitary  $U$  that disentangles the state

↪ Every state can be transformed to a product state

b) With symmetry: Two fix-point MPS  $\tilde{A}$  and  $\tilde{B}$  can be transformed by local unitaries iff both states have projective representations of the same class.

Example:  $\mathbb{Z}_2 \times \mathbb{Z}_2$  symmetry in  $S=1$  spin chain

Sufficient to look at two generators, e.g.  $R_x, R_z$ .

On-site representation in terms of  $S=1$  operators:

$$u_x = e^{i\pi S_x}, \quad u_z = e^{i\pi S_z} \quad (\text{linear representations})$$

Thus the MPS transforms as

$$\sum_k [u_x]_{jk} \Gamma_k = e^{i\theta_x} V_x \Gamma_k V_x^\dagger$$
$$R_{x/z}^2 = 1 \Rightarrow \theta_{x/z} = 0, \pi$$

$V_x, V_z$  can be linear or projective representations of  $\mathbb{Z}_2 \times \mathbb{Z}_2$ ,  
i.e.,  $V_x V_z = \pm V_z V_x$ .

$$\text{AKLT: } \Gamma^{-1} = \sqrt{\frac{2}{3}} \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad \Gamma^0 = \frac{1}{\sqrt{3}} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \Gamma^{+1} = -\sqrt{\frac{2}{3}} \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$$

$$u_z = \begin{pmatrix} -1 & & \\ & 1 & \\ & & -1 \end{pmatrix} \rightsquigarrow V_z = \sigma_z$$

$$[\text{e.g.}, \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \cdot \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \begin{pmatrix} 0 & -1 \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} 0 & -1 \\ 0 & 0 \end{pmatrix}]$$

$$u_x = \begin{pmatrix} & & -1 \\ & -1 & \\ -1 & & \end{pmatrix} \rightsquigarrow V_x = \sigma_x$$

$$\rightsquigarrow V_x V_z = -V_z V_x$$

$$|0\rangle|0\rangle: V_x = V_z = 1$$

$$\rightsquigarrow V_x V_z = \pm V_z V_x$$

- AKLT phase has degeneracies in the  $E_S$  since  $\Lambda$  commutes with  $V_x, V_z$  and  $V_x V_z = -V_z V_x$ .

$$\left[ \Lambda |\phi_n\rangle = \Lambda_n |\phi_n\rangle, \Lambda V_x |\phi_n\rangle = \Lambda_n \cdot V_x |\phi_n\rangle \text{ and } \langle \phi_n' | \phi_n \rangle = \sigma \right]$$

- AKLT can be generalized to higher spin  $S$

even  $S$  : fractionalization into integer spin  $\Rightarrow$  "trivial"

odd  $S$  : fractionalization into half-integer spin  $\Rightarrow$  SPTP

### Inversion symmetry

SPT can be protected by inversion symmetry

$$\begin{array}{ccc|ccc} 0 & 0 & 0 & 0 & 0 & 0 \\ -3 & -2 & -1 & 0 & 1 & 2 \end{array} : i = -i-1$$

MPS transforms as  $\Gamma \rightarrow \Gamma^T : \Gamma^T = \pm V \Gamma V^\dagger$  and  $V = \pm V^T$

### Time reversal symmetry

MPS transforms as  $\Gamma \rightarrow \Gamma^* : \Gamma^* = \pm V \cdot \Gamma V^\dagger$  and  $V = \pm V^T$

## 13.2 Signatures of SPT phases

How to detect an SPT? No local order parameter!

### Edge modes

Finite segment of an SPT has **sym. protected, gapless edge modes.**

Example: AKLT

  $\leadsto$  4-fold degeneracy of the ground state  
(e.g. Kramer's degeneracy on both ends)

String order parameter

Suppose the state  $|\Psi\rangle$  is invariant under  $g, h \in G$ ,  
such that  $[\otimes_j u_{g/h}^j] |\Psi\rangle = e^{i\theta} |\Psi\rangle$ .

Define the string order parameter as

$$S(g, X) = \left| \lim_{|i-j| \rightarrow \infty} \langle \Psi | X_i \left[ \otimes_{k=2}^{i-1} u_g^k \right] X_j | \Psi \rangle \right|$$

On the first glance:  $S$  should be non-zero for any state that is symmetric under  $g$ !

Turns out to be more subtle! If  $X$  is chosen appropriately,  $S$  can distinguish SPT phases. Use the MPS representation to understand  $S$ :

$$S(g, X) = \left| \Lambda^2 \left( \begin{array}{c} \Gamma \quad \Lambda \quad \Gamma \quad \Lambda \quad \Gamma \quad \dots \quad \Gamma \quad \Lambda \quad \Gamma \quad \Lambda \quad \Gamma \\ \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \\ \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \\ \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \\ \Gamma^* \quad \Lambda \quad \Gamma^* \quad \Lambda \quad \Gamma^* \quad \dots \quad \Gamma^* \quad \Lambda \quad \Gamma^* \quad \Lambda \quad \Gamma^* \end{array} \right) \Lambda^t \right|$$

$$= \left[ \sigma = \frac{V_2^+ \Gamma V_2}{\Gamma} \right]$$

$$= \left| \Lambda^2 \left( \begin{array}{c} \Gamma \quad \Lambda \quad \Gamma \quad \Lambda \quad \Gamma \quad \dots \quad \Gamma \quad \Lambda \quad \Gamma \quad \Lambda \quad \Gamma \\ \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \\ \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \\ \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \\ \Gamma^* \quad \Lambda \quad \Gamma^* \quad \Lambda \quad \Gamma^* \quad \dots \quad \Gamma^* \quad \Lambda \quad \Gamma^* \quad \Lambda \quad \Gamma^* \end{array} \right) \Lambda^t \right|$$

[Canon. Form!]

$$= \Lambda^2 \cdot V_3^\dagger \cdot V_3$$

Suppose that  $u_3 u_n = u_n u_3$  and  $V_n V_3 = e^{i\phi} V_3 V_n$

Choose  $X$  to have a particular quantum number under  $h$ :  $u_n X u_n^\dagger = e^{i\sigma} X$ .

The matrix  $X_{dd'}^L = \begin{matrix} d \\ \textcircled{X} \\ d' \end{matrix}$

transforms the same way under  $V_n$  [ $V_n X V_n^\dagger = e^{i\sigma} X$ ].

(similarly for  $X^R$  on the right)

$$\begin{aligned} \text{It follows that } \text{tr}[\Lambda X^L \Lambda V_3^\dagger] &= \text{tr}[V_n \Lambda X^L \Lambda V_3^\dagger V_n^\dagger] \\ &= e^{i(\sigma - \phi)} \cdot \text{tr}[\Lambda X^L \Lambda V_3^\dagger] \end{aligned}$$

$\leadsto$  Selection rule: String order vanishes if  $\phi \neq \sigma$ !

Vanishing string order in a symmetric phase is what is surprising!

Example:  $S=1$  chain with  $\mathbb{Z}_2 \times \mathbb{Z}_2$  sym.

$$S(g, X) = \left| \lim_{|i-j| \rightarrow \infty} \langle \Psi | S_i^z \left[ \prod_{k=2}^{n-1} e^{i\sigma S_k^z} \right] S_j^z | \Psi \rangle \right|$$

$$H = \sum [\vec{S}_i \cdot \vec{S}_{i+1} + D \cdot (S_i^z)^2]$$

## 13.2 Majorana chain revisited

Dimerized chain of Majorana Fermions:

Described by the Hamiltonian

$$H = i \sum_{j=1}^{L-1} \tau \gamma_{2j} \gamma_{2j+1} + i \sum_{j=1}^L \mu \gamma_{2j-1} \gamma_{2j}$$

which commutes with  $P = \prod_{j=1}^L [-i \gamma_{2j-1} \gamma_{2j}]$  (Parity symmetry).

Hamiltonian is real  $\gamma^2 = +1 \rightsquigarrow$  Class BDI with  $\mathbb{Z}$  top. phases

Stacking of chains:

Majorana modes cannot be coupled by quadratic terms as they violate  $\gamma^2 = 1$ !

What if we allow quartic terms (e.g.  $\gamma\gamma\gamma\gamma$ )?

Coupling 8 Majorana fermions with quartic term can "gap out" the edge mode  $\rightsquigarrow$  trivial phase

Thus  $\mathbb{Z} \rightarrow \mathbb{Z}_8$  in presence of interactions.

Different SPTs classified by how symmetries act on the edges:

- $P = P_L \cdot P_R$ ,  $P_L \cdot P_R = e^{-i\mu} P_R P_L$ ,  $\mu = 0, \pi$
- The way  $\gamma$  acts on the edges,  $\kappa = 0, \pi$
- Commutation relation of  $P$  and  $\gamma$ ,  $\phi = 0, \pi$

### 13.3 Bosonic SPT in 2D

#### Generalization of AKLT to 2D:

$S=2$  state on the square lattice.

A segment cut out of 2D plane:

- $\leadsto S = \frac{1}{2}$  degrees of freedom at the edge
- $\leadsto$  Can be removed if translation symmetry is broken (dimerization)
- $\leadsto$  SPT phase only if translation symmetry is preserved!

#### CZX-model: $\mathbb{Z}_2$ sym. protected SPT-phase

SPT that does not require translation symmetry.  
Consider a square lattice with four Ising spins per site:

Symmetry group generated by

$$U_{CZ} = U_X U_{CZ}$$

with  $U_X = \sigma_1^x \sigma_2^x \sigma_3^x \sigma_4^x$

$$U_{CZ} = CZ_{12} CZ_{23} CZ_{34} CZ_{41}$$

$$CZ = |00\rangle\langle 00| + |01\rangle\langle 01| + |10\rangle\langle 10| - |11\rangle\langle 11|$$

$\leadsto \mathbb{Z}_2$  group [ $U_{CZ}^2 = 1$ ]

Hamiltonian contains local terms around plaquettes

$$H = \sum_p H_p, \quad H_p = -X_4 \cdot P_2^a P_2^d P_2^i P_2^r$$

with  $X_4 = |0000\rangle\langle 1111| + |1111\rangle\langle 0000|$  and

$$P_2 = |00\rangle\langle 00| + |11\rangle\langle 11|$$

All terms commute  $\leadsto |\Psi_0\rangle = \bigotimes_p [ |0000\rangle + |1111\rangle ]$  unique GS, CZX sym.

Non trivial character at the boundary: Study reduced density matrix  $S$  for a block

Only degrees of freedom at the boundary are free.

$\leadsto$  Effective degrees of freedom  $|\tilde{1}\rangle = |11\rangle, |\tilde{0}\rangle = |00\rangle$

$(|\tilde{1}\rangle = |1\rangle, |\tilde{0}\rangle = |0\rangle$  at corner)

CZX sym. acts non trivially on the effective spins at boundary:

$$\tilde{U}_{\text{CZX}} = \prod_j \tilde{\sigma}_j^x \cdot \prod_j \tilde{c}_{z,j;j+1}.$$

Special symmetry:

(1) Not an on-site symmetry  
(independent of how we group the sites)

(2) No term with CZX symmetry can yield a unique, gap state at the boundary  $\leadsto$  SPT phase

Proof: Express  $\tilde{U}_{\text{CZX}}$  as matrix product unitary (MPU)

Combined symmetry operations:

$$P_{g_1, g_2} \equiv \frac{T(g_1)}{T(g_2)} P_{g_1, g_2} = \frac{T(g_1, g_2)}{T(g_2)} \leadsto P_{g_1, g_2} \text{ defined up to an arbitrary phase factor}$$

Non-trivial phase factors when combining three symmetry

$$\frac{\frac{T(g_1)}{T(g_2)} \frac{T(g_2)}{T(g_3)}}{\frac{T(g_1)}{T(g_3)}} = e^{i\Theta(g_1, g_2, g_3)} \frac{\frac{T(g_1)}{T(g_2)} \frac{T(g_2)}{T(g_3)}}{\frac{T(g_1)}{T(g_3)}} \quad (\text{same proj. on the right})$$

$\leadsto \Theta(g_1, g_2, g_3)$  form a 3-cocycle, classified by  $H^3(G, U(1))$

$\leadsto$  CZX is non-trivial!

No gapped state can have a sym. with non-trivial MPU!

(Assumption that the state can be expressed by MPS leads to contradiction  $\sim$  hexagon equation)

see Xie et al. PRB 84, 235141
